(54) Title: **PROCESS FOR MANUFACTURING MEMS**

(57) Abstract: The invention concerns a process for manufacturing a Micro-Electro-Mechanical-System (MEMS) comprising the use of a sacrificial layer, the process being characterized by the fact that the sacrificial layer is made of silicon. The invention also concerns MEMS devices such as SG-MOSEFT, MEMS switches or

MEMS tunable capacitors which may be obtained according to the previous cited process.

5

**Process for manufacturing MEMS****Field of the invention**

10 This invention concerns a process for manufacturing a Micro-Electro-Mechanical-System (MEMS).

The invention also relates to some MEMS device architectures that may be obtained according to this process.

15

**State of the art****SG-MOSFET:**

20 Suspended or movable gate Metal Oxide Semiconductor Field Effect Transistors (SG-MOSFET) have been extensively reported in the literature and a number of device architectures have been disclosed for various applications.

SG-MOFSET devices are disclosed in the following documents :

RF MEMS tunable capacitor and capacitive switch:

- 35 Tunable RF MEMS capacitors exploit the equilibrium between electrostatic and elastic forces applied to a movable conductive membrane and the related membrane displacement provides the tuning of the overall capacitor.

RF MEMS capacitive switches have an architecture very similar to a tunable capacitor, with the key difference that the metal membrane moves between two discrete states: up and down, acting on the capacitive coupling of a RF signal on an underneath metal layer that is covered by a thin insulator layer.

40

5

Consequently, a RF MEMS switch has two states 'off' and 'on', the late one obtained by pulling down the movable membrane with an applied voltage. MEMS switches have advantages in terms of low power consumption, low cost, linearity and potential compatibility with integrated circuits.

10

Capacitive RF MEMS switches and Tunable MEMS capacitors are disclosed in the following documents :

20

None of the types of inventions or publications referred hereto uses architectures with metal-over-gate SG-MOSFET, Capacitive RF MEMS switch or Tunable MEMS capacitor which may be made with a technological process based on dry etching of a silicon sacrificial layer and metals as suspended layers. The material of the suspended gate of prior art reports is polycrystalline silicon (polysilicon) and the sacrificial layers are silicon dioxide (SiO<sub>2</sub>) or polymers. But the prior art never teaches to use silicon as sacrificial layer. In addition, most of the prior art processes use wet etching to release the suspended structures.

25

### 30 Summary of the invention

It is therefore an object of the present invention to provide an improved process to manufacture MEMS devices.

35 Another object of the invention is to provide new MEMS devices architectures.

Those and other objects are accomplished with the process as defined in claim 1.

- 5 The thickness of the Si sacrificial layer may range from few tens of nm to few tens of  $\mu\text{m}$ .

The invention is particularly useful for the manufacture of a SG-MOFSET.

- 10 It is also particularly advantageous for the manufacture of an architecture using two metal layers that can be used both for capacitive RF switch and tunable MEMS capacitor. It includes two dielectric layers, each in contact with one of the metals. The upper dielectric is not mandatory and same structure can be used for same applications without this layer: It can however offer some advantages, at  
15 least in terms of extended stability of the structure. For the capacitive switch, a high-k dielectric layer may be added on the first metal layer to have a high capacitance ratio between 'on' and 'off' states. The final MEMS structure is released with dry etching of sacrificial silicon. It is worth noting that the overall process can be considered a surface micro-machining process for which the  
20 sacrificial layer is silicon and the body of the MEMS devices is a metal.

- The invention may be also particularly useful for co-integration of MEMS devices with CMOS integrated circuits. In case of the use of polysilicon as sacrificial layer, SG-MOSFETs are realized in-CMOS process. In case of the use of  
25 amorphous silicon as sacrificial layer, the proposed process is low temperature ( $<450^{\circ}\text{C}$ ) and can be used as post-CMOS process.

Some detailed examples of the invention will be discussed hereafter, with the support of the following figures :

30

Brief description of the drawings :

- FIG. 1:** Cross sections of the suspended-gate MOSFET: (a) architecture on Silicon-On-Insulator, (b) architecture on silicon substrate and (c) architecture with  
35 the underneath silicon substrate etched. The gate is made of metal in all cases and its displacement is vertical.

**FIG. 3:** Design of a SG-MOSFET with lateral Hall contacts for silicon magnetic sensor with tunable sensitivity.

10

**FIGS. 4.1-4.11:** Detailed description of the SG-MOSFET technological process.

**FIG. 5:** Cross section and principle of the metal-metal tunable MEMS capacitor provided by the full-dry etching of sacrificial amorphous silicon: (a) architecture  
15 with one air-gap, (b) architecture with two air-gaps and separated electrostatic actuation, and (c) architecture with gradual air-gap.

**FIG. 6:** Cross section and principle of the metal-metal MEMS switch with high-k dielectric.

20

**FIGS. 7.1-7.10:** Detailed description of the tunable metal-metal MEMS capacitor technological process. On the left one air-gap, on the right two or more air-gaps (multi-air-gaps).

25 **SG-MOSFET architecture and principle :**

The cross section and the principle of the SG-MOSFET are depicted in Figs. 1: it combines in a top-down architecture a suspended metal membrane used as  
movable gate with a MOS transistor. This architecture is nor a pure MEMS  
30 device nor a pure solid-state device, but a hybrid combination of both. When its gate voltage,  $V_g$ , is increased, the intrinsic gate-voltage,  $V_{gint}$ , which drives the MOS channel formation, is tuned according to a capacitor divider:

$$V_{gint} = \frac{V_g}{1 + C_{gcint} / C_{gap}}$$

where  $C_{gcint}$ ,  $C_{gap}$  are the intrinsic gate-to-channel capacitance of the underneath  
35 MOSFET and the air-gap capacitance, respectively. The membrane moves

- 5 continuously downwards as long as the equilibrium is maintained between electrostatic and elastic forces:

$$|F_{\text{elastic}}| = kx = \frac{1}{2} \frac{\epsilon_{\text{air}} A (V_g - V_{g\text{int}})^2}{(t_{\text{gap0}} - x)^2} = |F_{\text{electr}}|$$

- where  $k$  is the equivalent elastic constant of the gate,  $x$  is the gate displacement,  $t_{\text{gap0}}$  the initial air-gap dimension and  $V_{g\text{int}}$  the intrinsic (or internal) gate voltage.
- 10 When  $V_g$  equals the pull-in voltage,  $V_{\text{PI}}$ , unstable equilibrium is reached and the switch (suspended membrane) moves from the 'off' to the 'on' state.

Some unique characteristics of the SG-MOSFET are mentioned below:

- (i) the *dynamic threshold voltage*: low in the 'on' state and high in the 'off' state, which is a key advantage for RF switch use because of a higher isolation in the 'off' state compared to the solid-state MOSFET;
  - (ii) the *super-exponential* dependence of  $Q_{\text{inv}}$  vs.  $V_g$  in the sub-threshold region, that can result in local sub-threshold slope better than the ideal limit of 60mV/decade of any conventional MOSFET and the *super-linear* dependence of  $Q_{\text{inv}}$  vs.  $V_g$  in moderate and strong inversions;
  - (iii) the possibility to provide RF switches with capacitance ratios between 'on' and 'off' states better than 100;
  - (iv) the possibility to use the SG-MOSFET as tunable capacitor with tuning range better than any other similar MEMS capacitor.
  - 25 (v) the possibility to use the SG-MOSFET as a capacitive or current switch (current could be driven when a voltage is applied on the drain when the source is grounded), both with better isolation in the off state (up position) compared with a solid state-device like a conventional MOSFET.
- 30 In reference [SG8] we have proposed the first unified analytical model of this device, including all regimes of operation.

The key parameters of the SG-MOSFET architecture depicted in FIGS. 1 and 2 are: the thickness of the initial air-gap, the thickness of Insulator 1, the thickness of Insulator 2, the equivalent elastic constant  $k$  depending of the arm material and on their design, the surface of the metal suspended gate membrane.

35

5

FIGS. 2 a, b, c present some typical designs of the suspension arms of the movable gate that directly impact on the equivalent k constant and then, on the value of the voltage needed to control the operation of the device: switching between 'on' and 'off' states or tuning of the gate capacitance. With the architecture and the technological process proposed herewith, the device operation can be achieved with voltages less than 5V, which makes it totally compatible with CMOS.

#### SG-MOSFET applications :

15

The following applications of the SG-MOSFET are proposed:

1. SG-MOSFET as Radiofrequency (RF) MEMS capacitive (contactless) switch when the gate is electrostatically moved from 'off' (up) to 'on' (down) states;
2. SG-MOSFET as Radiofrequency (RF) MEMS tunable capacitor when the gate is electrostatically moved under equilibrium;
3. SG-MOSFET as MOSFET current switch when the gate is electrostatically switched between 'off' and 'on' states;
4. SG-MOSFET as integrated CMOS accelerometer wherein the acceleration is converted in vertical gate displacement and furthermore in variation of the drain current based on unique device;
5. SG-MOSFET as magnetic field sensor (MAGFET) with tunable sensitivity to a magnetic field perpendicular to the gate surface, accordingly to the displacement of the suspended gate under electrostatic forces.

#### Process for manufacturing a SG-MOSFET :

The fabrication of a SG-MOSFET in accordance with the present invention will be described with reference to FIGS. 4.1 to 4.11. The manufacturing process presented here is fully compatible with standard CMOS processes. A silicon substrate 01 is initially cleaned by conventional techniques and a field oxide layer 02, whose thickness is about 500nm, is grown in a wet atmosphere. Substrate 01 is <100> p-type silicon having a resistivity between 0.1-0.5  $\Omega\text{cm}$ . Alternatively, n-

- 5 type Si substrate can also be used. Silicon-on-insulator (SOI) substrates are preferably used for RF applications to have high resistivity substrates. Using conventional photolithography techniques, the active device areas are formed by wet etching in a BHF (7:1) solution. The resulting structure is shown in FIG. 4.1.
- 10 The substrate 01 is then cleaned and a gate oxide layer 03 is thermally grown in a dry atmosphere as shown in FIG. 4.2. The thickness range is between 100 to 1000 Å.

Next, as shown in FIG. 4.3, a silicon sacrificial layer 04 is deposited on the surface of the structure. The sacrificial layer 04 can be amorphous silicon or polysilicon. Amorphous silicon is deposited by different kind of techniques: physical vapor deposition techniques, i.e. evaporation, RF or DC sputtering, and chemical vapor deposition techniques, i.e. low pressure chemical vapor deposition (LPCVD) or plasma enhanced chemical vapor deposition (PECVD). Polysilicon is deposited by LPCVD but can also be obtained from amorphous silicon after thermal annealing. The thickness range is between 100 nm to 2 µm. As shown in FIG. 4.4, the sacrificial layer 04 is then covered by a SiO<sub>2</sub> diffusion barrier layer 05, whose thickness is comprised between 1 nm to 100 nm. This layer prevents diffusion between the Si sacrificial layer 04 and the aluminum metal gate membrane 07. The barrier layer 05 can be obtained by dry oxidation of the Si sacrificial layer 04 or by deposition of a SiO<sub>2</sub> layer even by RF sputtering or by LPCVD (low temperature oxide (LTO); SiO<sub>2</sub>, phosphosilicate glass (PSG) or borophosphosilicate glass (BPSG)). Using conventional photolithography techniques, the diffusion barrier layer 05 is patterned even by wet etching in BHF or HF solution or by dry etching technique based on C<sub>x</sub>F<sub>y</sub> RIE plasma process as shown in FIG. 4.5. The patterning of Si sacrificial layer 04 have to be anisotropic and highly selective on thin gate oxide 03. This can be performed by cryogenic SF<sub>6</sub>/O<sub>2</sub> chemistry process or chlorine-based chemistry using inductively coupled plasma (ICP) reactors. The resulting structure is shown in FIG. 4.6.

5 Then, as shown in FIG. 4.7, source and drain regions 06 are formed in silicon substrate 01 using conventional self-aligned process. It should be noted that our Si sacrificial layer 04 plays the role of polysilicon gate in standard CMOS processes. Phosphorus or arsenic ions are implanted in case of p-type substrate to formed n-doped source and drain regions 06. For example, phosphorous ions  
10 are implanted at an energy of 25 keV and a dose of  $2 \times 10^{15}$  ions/cm<sup>2</sup>. Alternatively, boron ions are implanted for n-type substrate to formed p-doped source and drain regions 06. The structure is then annealed in a nitrogen atmosphere, to avoid the oxidation of the silicon sacrificial layer 04 side walls, at 950°C, to repair damage to silicon substrate 01 due to implantation.

15 Next, as shown in FIG. 4.8, the gate oxide layer 03 is patterned by wet etching in a BHF solution to open contact holes to source and drain regions 06. Similarly, holes to contact the substrate 01 are opened.

20 The metal gate membrane layer 07 is then deposited on the surface of the structure as shown in FIG. 4.9. This layer also served as metal contacts to source and drain regions 06 and to substrate 01. For example, a 0.8μm thick aluminum-silicon (with 1% silicon) is deposited by sputtering. Using conventional photolithography techniques, the aluminum gate membrane and the suspension  
25 arms are patterned by chlorine-based plasma chemistry or by wet etching in a standard ANP solution. The resulting structure is shown in FIG. 4.10.

The accelerometer application of SG-MOSFET needs a higher mass of the gate membrane in order to increase sensor sensitivity to acceleration without  
30 changing the rigidity of the suspension arms. This can be done by depositing a thicker metal layer 07. Then, the metal gate membrane is patterned by partial etching of the metal layer 07. After another photolithographic step, the suspension beams are formed.

35 Next, the diffusion barrier layer 05 is patterned even by dry etching technique based on C<sub>x</sub>F<sub>y</sub> RIE plasma process or by wet etching in NH<sub>4</sub>F solution, with high selectivity to aluminum, to have an access to the silicon sacrificial layer 04.

5

Finally, the suspended metal gate membranes are released by dry etching in a fluorine-based chemistry with high selectivity to SiO<sub>2</sub> thin gate oxide layer 03 and metal layer 07, as shown in FIG. 4.11.

10 Metal-metal RF MEMS switch and tunable capacitor architecture and principle :

The cross section of the MEMS tunable capacitor proposed device is described in FIGS. 5 : It uses two metal layers, capped with two insulators (Insulators 1 and 2) separated by different air-gaps. Metal 1 is deposited on top of another  
15 insulator called Insulator 0 that can be SiO<sub>2</sub>. The movable metal membrane is defined by Metal 2 and its vertical displacement is controlled by the applied voltage.

FIG. 5a shows a simple air-gap tunable capacitor which has a capacitance tuning  
20 range limited by the pull-in effect.

FIG. 5b presents an architecture with two air-gaps (Air-gap 1 and Air-gap 2, Air-gap 1 is designed larger than Air-gap 2) wherein the capacitance tuning range is significantly enlarged because the equilibrium region between electrostatic and  
25 elastic forces is enlarged.

The difference with respect to other publications that proposes also the use of two air-gaps is that, our architecture uses two insulator layers over the metals, resulting in different characteristics, and the releasing process is completely  
30 different, with amorphous silicon as sacrificial layer. Moreover much more aggressively scaled dimensions in terms of air-gaps can be addressed with our structure. Advantages of better yield and fully compatible CMOS process can be mentioned. Also, by the proper design of the suspension arms (with meanders), a low voltage, CMOS-compatible, operation can be achieved for this structure.  
35 Another advantage of our technological process is that it is compatible for multi-air-gaps and gradual air-gaps (see FIG.5c) architectures which lead to increase properties compared with two-air-gaps structures.

5

This technological process can be used for both MEMS RF capacitive switch and tunable capacitor applications. For the capacitive switch, we add a high-k dielectric layer between Metal 1 and Insulator 1 to get a high capacitance ratios between 'on' and 'off' states (see FIG. 6).

10

Metal-metal MEMS device applications :

The following applications of the metal-metal MEMS device architecture are proposed:

- 15 1. Radiofrequency (RF) MEMS capacitive (contactless) switch when the gate is electrostatically moved from 'off' (up) to 'on' (down) states;
2. Radiofrequency (RF) MEMS tunable capacitor when the gate is electrostatically moved under equilibrium;
3. Integrated CMOS accelerometer wherein the acceleration is converted in  
20 vertical displacement of the membrane and furthermore in variation of the capacitance.

Process for manufacturing a metal-metal MEMS switch or a tunable capacitor:

- 25 The fabrication of metal-metal tunable capacitors and switches in accordance with the present invention will be described with reference to FIGS. 7.1 to 7.10. The method of fabrication presented here is fully compatible with CMOS post-processing. A silicon substrate **01** is initially cleaned by conventional techniques and a silicon dioxide layer **02** is grown in a wet atmosphere as shown in FIG. 7.1.
- 30 The thickness range is between 0.2 to 2  $\mu\text{m}$ . A low temperature oxide (LTO) deposited by LPCVD can replace the wet oxidation. Silicon-on-insulator (SOI) substrates are preferably used for RF applications to have high resistivity substrates.
- 35 Then, the first metal layer **03** is deposited on the surface as shown in FIG. 7.2. A 1  $\mu\text{m}$  thick aluminum-silicon layer (with 1% silicon) is sputtered. Using conventional photolithography techniques, the aluminum base electrodes and the

- 5 contact pads are patterned by chlorine-based plasma chemistry or by wet etching in a standard ANP solution as shown in FIG. 7.3.

For the fabrication of capacitive switches, a dielectric layer with high dielectric constant (high-k dielectric) is deposited and patterned by dry plasma chemistry  
10 on the first metal layer 03. The high-k dielectric can be sputtered or PECVD silicon nitride or sputtered TiO<sub>2</sub>.

As shown in FIG. 7.4, the structures are then covered by a SiO<sub>2</sub> diffusion barrier layer 04, the thickness of which is comprised between 10 to 100 nm. This layer  
15 will prevent diffusion between the silicon sacrificial layer 05 and the aluminum base electrodes. The barrier layer 04 can be obtained by deposition of a SiO<sub>2</sub> layer even by RF sputtering or by LPCVD (low temperature oxide (LTO): SiO<sub>2</sub>, phosphosilicate glass (PSG).

20 Next, as shown in FIG. 7.5, an amorphous silicon sacrificial layer 05 is deposited on the surface of the structure. Amorphous silicon is deposited by different kind of techniques: physical vapor deposition techniques, i.e. evaporation, RF or DC sputtering, and plasma enhanced chemical vapor deposition (PECVD). The thickness range is between 100 nm to 3 μm.

25 The patterning of amorphous silicon sacrificial layer 05 is performed by chlorine- or fluorine- based chemistry process using inductively coupled plasma (ICP) reactors. Several photolithographic steps are needed to provide the three-dimensional membrane shape and multi-air-gaps architecture. The first steps  
30 consist in thinning the silicon sacrificial layer 05 to define the different air-gaps as shown in FIG. 7.6. The second step consists in passing through the silicon sacrificial layer 05 to prepare the mechanical anchors to the substrate 01 for the suspended membranes. The resulting structure is shown in FIG. 7.7.

35 As shown in FIG. 7.8, the patterned sacrificial layer 05 is then covered by a SiO<sub>2</sub> diffusion barrier layer 06, those thickness is comprised between 10 to 100nm. The second metal layer 07 is then deposited on the surface of the structure. A

- 5    1 $\mu$ m thick aluminum-silicon (with 1% silicon) is sputtered. Using conventional photolithography techniques, the aluminum membrane and the suspension beams are patterned even by chlorine-based plasma chemistry or by wet etching in a standard ANP solution. The resulting structure is shown in FIG. 7.9. Next, the diffusion barrier layer 06 is patterned by dry etching technique based on C<sub>x</sub>F<sub>y</sub>
- 10   RIE plasma process to have an access to silicon sacrificial layer 05.

Then, the suspended metal membranes are released by dry etching of the silicon sacrificial layer 05 in a fluorine-based chemistry with a high selectivity to SiO<sub>2</sub> and aluminum as shown in FIG. 7.10. Finally, the diffusion barrier layer 04 on

15   electric contacts is removed by anisotropic C<sub>x</sub>F<sub>y</sub> RIE plasma process.

5

## Claims

1. Process for manufacturing a Micro-Electro-Mechanical-System (MEMS) comprising the use of a sacrificial layer characterized by the fact that the sacrificial layer is made of silicon.
2. Process according to the previous claim wherein the silicon sacrificial layer is removed by plasma etching with fluorine-based chemistry.
3. Process according to claim 1 wherein the silicon sacrificial layer is removed by xenon difluoride ( $\text{XeF}_2$ ) or bromine trifluoride ( $\text{BrF}_3$ ) etching.
4. Process according to claim 1 wherein the silicon is in polycrystalline form.
5. Process according to claim 1 wherein the silicon is in amorphous form.
6. Process according to anyone of the previous claims characterized by the fact that it is used in surface micromachining.
7. Process according to anyone of the previous claims characterized by the fact that it is used for the manufacture of a MEMS containing a suspended metal layer.
8. MEMS device architecture obtained according to the process as defined in anyone of the previous claims.
9. MEMS device according to the previous claim to be fabricated on silicon, silicon-on-insulator substrates and on silicon with the underneath substrate etched.
10. MEMS device according to claim 8 or 10 characterized by the fact that it comprises a suspended metal gate.

- 5
11. MEMS device according to the previous claim characterized by the fact that it is a suspended gate MOSFET.
12. MEMS device according to claim 10 or 11, wherein said metal is aluminum,  
10     AlSi, AlSiCu, copper, gold, tungsten, platinum, titanium or a combination of these metals.
13. MEMS device architecture obtained according to the process as defined in  
15     anyone of the previous claims 1 to 7 and using two metal levels, one fixed and one movable, called membrane, both capped with one insulator, with variable air-gaps and an underlying insulator deposited on a semiconductor substrate.
14. MEMS device according to the previous claim characterized by the fact that it  
20     comprises a high-k dielectric made of  $\text{TiO}_2$ .
15. Use of the device of claim 10 as radiofrequency capacitive switch.
16. Use of the device of claim 10 as current switch.
- 25
17. Use of the device of claim 10 as radiofrequency tuneable capacitor.
18. Use of the device of claim 10 as magnetic field sensor.
- 30
19. Use of the device of claim 10 as accelerometer.
20. Use of the device of claim 10 as pressure sensor.

PCT/CH 02/00490

## Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple Inventions in this International application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☒ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

### Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
